The Kerberos Authentication System

Brad Karp UCL Computer Science

CS GZ03 / M030 28th November 2016

Why Study Kerberos?

- One of most widely used authentication systems, implemented in many, many UNIXes for a variety of services
- Simple example of use of cryptography to solve practical authentication problems
- Imperfect; weaknesses instructive

Kerberos: Goals

- Authentication of diverse entities, for diverse services:
 - Users, client machines, server machines
 - File systems, remote login, file transfer, printing, &c.
- Authentication in an "open environment"
 - Users may be superuser on their own workstations (so may adopt any user ID if credentials over network unauthenticated); hardware not centrally controlled
 - Same user population may use many machines and services (e.g., labs of public-access machines on a campus)
- Drop-in replacement of passwords for preexisting protocols
 - Convenient; strength of security?

Kerberos Model: Central Authority

- Within a site (e.g., MIT), a central database server stores names and secret keys for all principals
 - Keys are for 56-bit DES symmetric-key cipher
 - Now brute-forceable; more reasonable at time of Kerberos' first use (1988)
- All users and machines are principals, named with human-readable names
- All principals trust central database server

Kerberos Principal Names

- Users: e.g., bkarp
 - Can have instances; sub-names of a principal, e.g., bkarp.mail, bkarp.root
- Machines: e.g., boffin, arkell, sonic
- Services: e.g., rlogin.sonic (instance of the rlogin service running on sonic)
- Site name: realm; all machines in one administrative domain share one central Kerberos database, in same realm
- name.instance@realm, e.g., bkarp@UCL.AC.UK

Kerberos Protocol

- Goal: mutually authenticated communication
 - Two principals wish to communicate
 - Principals know each other by name in central database
 - Kerberos establishes shared secret between the two
 - Can use shared secret to encrypt or MAC subsequent communication
 - [Few "Kerberized" services encrypt, and none MAC!]
- Approach: leverage keys shared with central database
 - Central database trusted by/has keys for all principals

Kerberos Credentials

- Client can either be user or machine, depending on context
- To talk to server s, client c needs shared secret key and ticket:
 - Session key: K_{s,c} (randomly generated by central database)
 - Ticket:
 - $T = \{s, c, addr_c, timestamp, lifetime, K_{s,c}\}_{K_s}$ (where K_s is key s shares with database)
 - Only server s can decrypt ticket

Kerberos Credentials (2)

- Given ticket, client creates authenticator:
 - Authenticator:
 - A = {c, addr_c, timestamp}_{K_{s,c}}
 - Client must know K_{s,c} to create authenticator
 - Authenticator can only be used once
- Client presents both ticket T and authenticator A to server when requesting an operation
 - T convinces server that $K_{s,c}$ was given to c
 - A intended to prevent replay of requests
- "Kerberized" protocols use authenticator in place of password

Getting the User's First Ticket

- User logs in at console with username and password (username is Kerberos name)
- Kerberized login program retrieves initial ticket for user:
 - Client machine sends to Kerberos database:
 c, tgs
 (tgs is principal name for ticket-granting service)
 - Server responds with:
 - { $K_{c,tgs}$, { $T_{c,tgs}$ }_{K_{tgs}}}_{K_c}
 - where
 - $T_{c,tgs} = tgs, c, addr_c, timestamp, lifetime, K_{c,tgs}$
 - Client decrypts server's response with $K_c = H(password)$

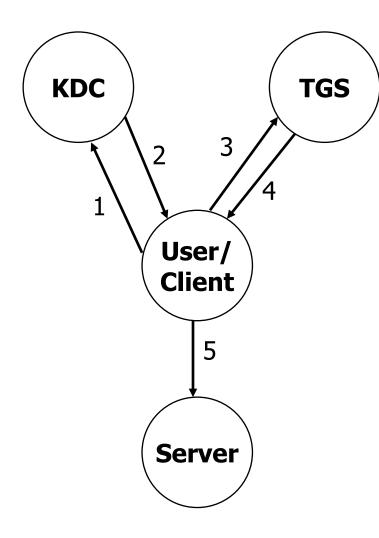

Requesting a Service

- Client c (e.g., user bkarp) wishes to use a service on s, already holds K_{c,tgs}
- Client requests ticket from tgs as follows:
 - Client sends to tgs:
 - $s_{,} \{T_{c,tgs}\}_{K_{tgs}}, \{A_{c}\}_{K_{c,tgs}}$
 - tgs replies to client with ticket for service on that server:
 - $\{\{\mathsf{T}_{c,s}\}_{K_s}, K_{c,s}\}_{K_{c,tgs}}\}$
 - where K_{c,s} is a new, randomly generated session key for use between c and s

Using a Service

- Once client holds ticket for service, uses it with authenticator to request operation from server:
 - Client sends to s: service name, {T_{c,s}}_{K_s}, {A_c}<sub>K_{c,s}
 </sub>
 - Server validates $T_{c,s}$ and A_{c} , and executes operation if they are valid
- Server uses timestamps and expiration times to invalidate stale, "future", replayed requests

Kerberos: Summary of Message Flow

- 1. Request for TGS ticket: c, tgs
- 2. Ticket for TGS:
 - $\{K_{c,tgs}, \{T_{c,tgs}\}_{K_{tgs}}\}_{K_{c}}$
- 3. Request for Server ticket:
 - s, $\{T_{c,tgs}\}_{K_{tgs}}$, $\{A_c\}_{K_{c,tgs}}$
- 4. Ticket for Server:
 - $\{\{\mathsf{T}_{\mathsf{c},\mathsf{s}}\}_{\mathsf{K}_{\mathsf{s}}},\mathsf{K}_{\mathsf{c},\mathsf{s}}\}_{\mathsf{K}_{\mathsf{c}},\mathsf{tgs}}\}$
- 5. Request for Service: service name, {T_{c,s}}_{K_s}, {A_c}_{K_{c,s}}

Ticket Lifetime

- How should we choose ticket lifetimes?
- Convenience: longer ticket-granting ticket
 lifetime → user must type password less often
- Performance: longer service ticket lifetime → client must request new service ticket less often
- Risk: longer ticket lifetime lengthens period when ticket can be stolen, abused
- MIT Athena implementation destroys ticketgranting ticket when user logs out

Kerberos Security Weaknesses

- Vulnerability to replay attacks; default authenticator lifetime 5 minutes
- Reliance on synchronized clocks across nodes
- Storage of tickets on workstations
- No way to change compromised password securely
- Key database focal point for attack
- Hard to upgrade key database (relied on by all nodes in system)

Kerberos User Inconveniences

- Large (e.g., university-wide) administrative realms:
 - University-wide admins often on critical path
 - Departments can't add users or set up new servers
 - Can't develop new services without central admins
 - Can't upgrade software/protocols without central admins
 - Central admins have monopoly servers/services (can't set up your own without a principal)
- Rigid; what if user from realm A wants to authenticate himself to host at realm B?
- Ticket expirations
 - Must renew tickets every 12-23 hours
 - How to create long-running background jobs?
