

# ***C340 Concurrency: Modelling Processes***

***Wolfgang Emmerich  
Mark Levene***

# *Processes and Threads*

- *Execution of a program is a process*
- *Concurrent programs consist of multiple processes*
- *Threads are lightweight processes*
- *Both threads and processes can be modelled in the same way*
- *We use finite state machines for that*

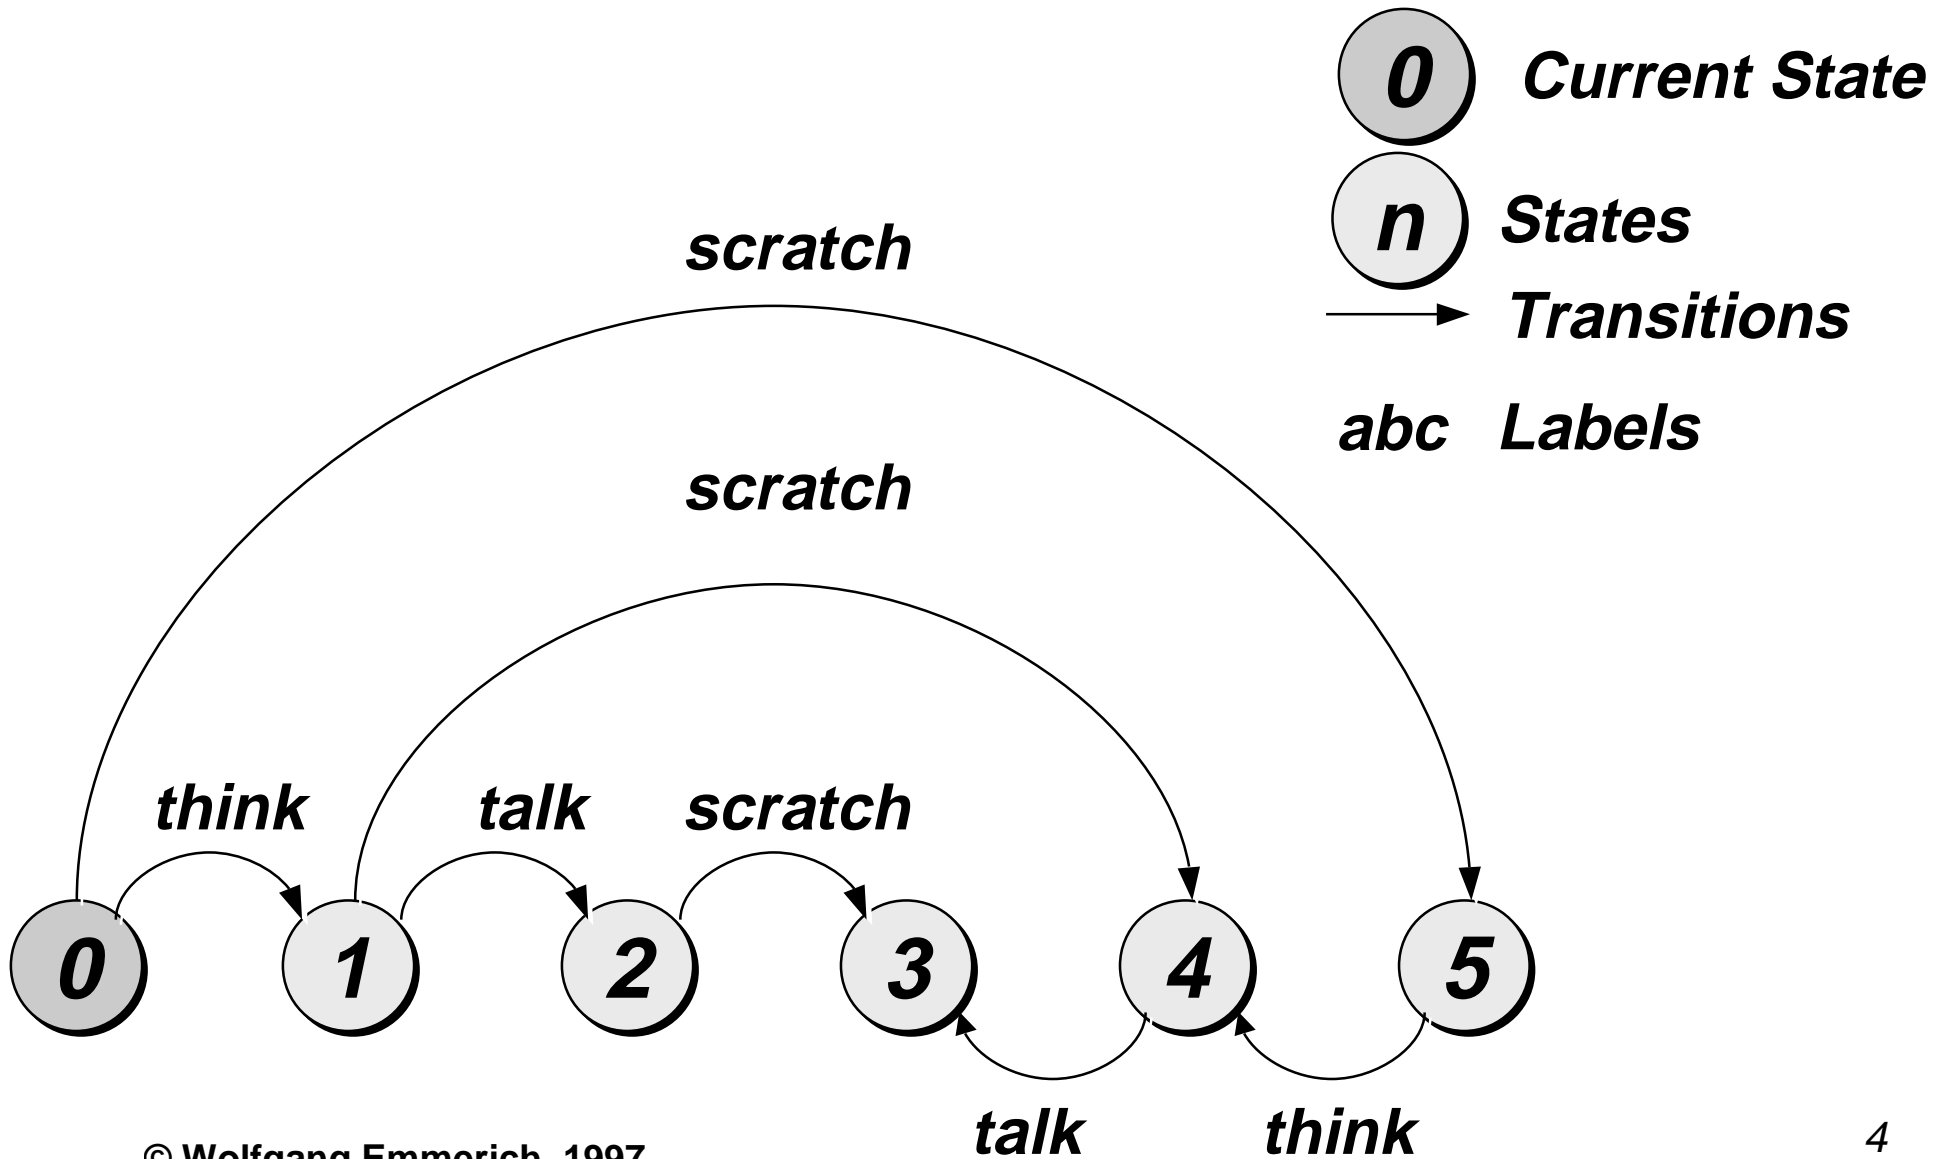

# *Labelled Transition Systems*

- *Special form of finite state machines*
- *Used to model states of concurrent programs and transitions between them*
- *LTS* :=  $(S, T, A, \delta, c)$  where
  - *S (a finite set of states)*
  - *$T \subseteq S \times S$  (a finite set of transitions)*
  - *A (an alphabet of atomic actions)*
  - *$\delta: T \rightarrow A$  (a transition labelling)*
  - *$c \in S$  (the current state)*

# Graphic LTS Notation

# *LTS Semantics*

- *All actions that are annotations of transitions starting from the current state are enabled*
- *If process engages in enabled action target of transition becomes current state*

*Demo*

- *In this way LTS determines all possible traces of process*

# *Finite State Processes (FSP)*

- *LTS become unmanageable for large number of states and transitions*
- *Process algebras determine LTSs in a more concise way*
- *Finite State Processes (FSP): machine readable notation for a process algebra*
- *For each FSP model an equivalent LTS can be constructed automatically*

# *FSP Intro: Action Prefix*

- *Let  $x$  be an action and  $P$  a process. The action prefix  $(x \rightarrow P)$  is process that initially engages in action  $x$  and then behaves in the same way as process  $P$*
- *Used to model atomic actions*
- *Actions have lower case identifiers, states have upper case identifiers*
- *Example:  $\text{ONESHOT} = (\text{once} \rightarrow \text{STOP})$ .*
- *Equivalent LTS:*

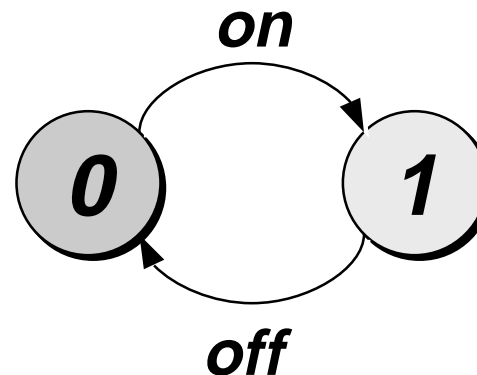

# FSP Intro: Recursion

- *Let  $P$  be a process. Then  $P$  may be used in action prefixes in a recursive way.*
- *Used to model repetitive behaviour*
- *Example: SWITCH=OFF.*

OFF = (on -> ON) .

ON = (off -> OFF) .

- *Equivalent LTS:*

- *Note: Processes are equivalent to states*

# *FSP Intro: Local Processes*

- *It is not necessary for all states/processes to be globally visible.*
- *Restricting states/processes by use of ‘,’*
- *Example:*  
SWITCH=OFF ,  
OFF= ( on -> ON ) ,  
ON= ( off -> OFF ) .
- *OFF and ON are not visible outside SWITCH*
- *Equivalent to:*  
SWITCH= ( on -> off -> SWITCH ) .

# FSP Intro: Choice

- $(x \rightarrow P \mid y \rightarrow Q)$  describes a choice that engages either in  $x$  or  $y$ . After  $x$  it continues with  $P$ , after  $y$  it continues with  $Q$

- *Example:* DRINKS = (

red  $\rightarrow$  tea  $\rightarrow$  DRINKS

| blue  $\rightarrow$  coffee  $\rightarrow$  DRINKS

) .

- *Equivalent LTS:*

# *FSP Intro: Indexes*

- *A range type is a finite and scalar type:*
- *Example: range T=0..3*
- *If T is a range type then  $x[i:T]$  is the declaration of an action index and  $P[i:T]$  is declares an indexed process.*
- *A process index variable is valid within the process, an indexed action is valid within the scope of the choice.*

# FSP Intro: Index Example

```
const N = 1
range T = 0..N
range R = 0..2*N
SUM      = (in[a:T][b:T] -> OUT[a+b],
OUT[s:R] = (out[s] -> SUM).
```

## ■ Equivalent LTS:

# FSP Intro: Guarded Actions

- **The guarded action when  $B \ x \rightarrow P$  means that when the guard  $B$  is true action  $x$  is enabled and the process proceeds as  $P$ .**

- **Example:**

```
COUNT(N=3) = COUNT[0],  
COUNT[i:0..N] = (when(i < N) inc -> COUNT[i+1]  
                  | when(i > 0) dec -> COUNT[i-1]  
                  ).
```

- **Equivalent LTS:**

# Summary

---

- ***Formal Definition of LTS***
- ***Algebraic notation in FSP***
- ***Equivalence between LTS and FSP***
- ***FSP and LTS concepts introduced so far are sufficient for sequential programs***
- ***Next session: FSP constructs for modelling concurrent programs***
- ***Solve Exercises 1 and 2 of tutorial sheet***
